# OFF-DESIGN PERFORMANCE OF CSP PLANT BASED ON SUPERCRITICAL CO<sub>2</sub> CYCLES

Dario Alfani, Marco Astolfi, Marco Binotti, Paolo Silva, Ennio Macchi  
*Politecnico di Milano, Milano, Italy*

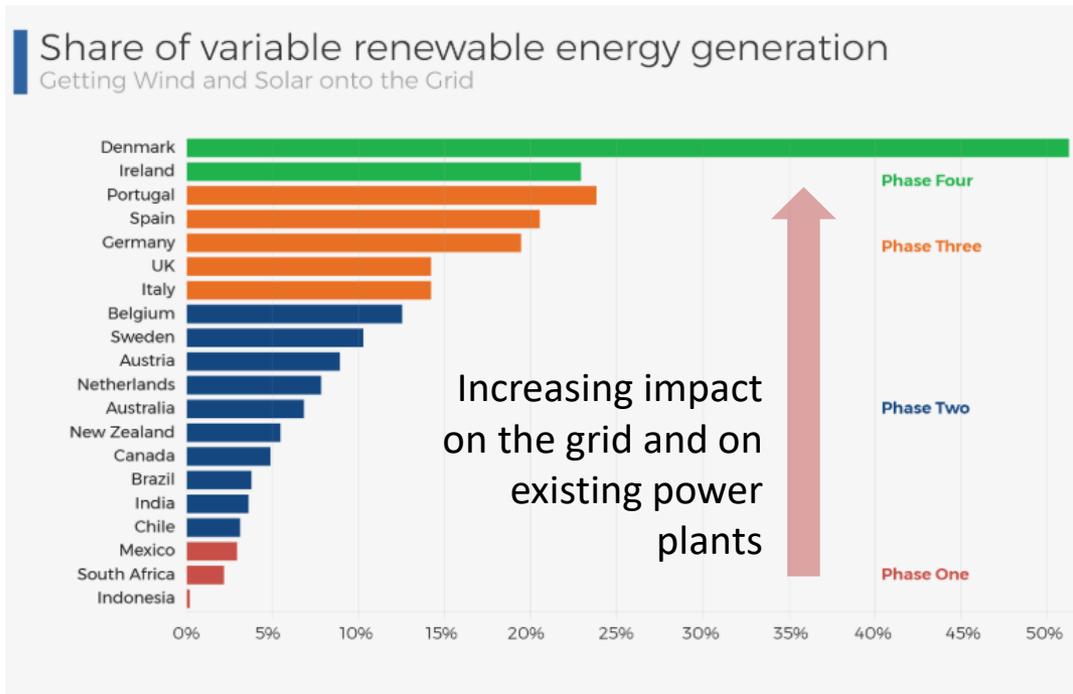

SolarPaces Conference, 1- 4 October 2019, Daegu, South Korea

- Introduction
- The H2020 sCO<sub>2</sub>-Flex Project
- Scope of the work
- Cycle and Heat Exchangers Design
- Off-design Simulation: Methodology and Assumptions
- Part Load Analysis
- Variable Ambient Temperature Analysis
- Conclusions and Future Steps

# Introduction – Future Energy Scenario

- The fraction of **Variable Renewable Energy (VRE)** in the EE generation has already exceeded 10% in 9 countries

	Phase Three	Phase Four
<b>Characterisation from a system perspective</b>	Flexibility becomes relevant with greater swings in the supply/demand balance	Stability becomes relevant. VRE capacity covers nearly 100% of demand at certain times
<b>Impacts on the existing generator fleet</b>	Greater variability of net load. Major differences in operating patterns; reduction of power plants running continuously	No power plants are running around the clock; all plants adjust output to accommodate VRE
<b>Impacts on the grid</b>	Significant changes in power flow patterns across the grid, driven by weather condition at different locations; increased two-way flows between high and low voltage parts of the grid	Requirement for grid-wide reinforcement, and improved ability of the grid to recover from disturbances
<b>Challenges depend mainly on</b>	Availability of flexible resources	Strength of system to withstand disturbances

Less material compatibility problems @high T

**Can sCO<sub>2</sub> cycles be the solution for flexibility in the power sector?**

**(?) High Part Load Performance**

**(?) Fast Transient – Low Inertia**

# The H2020 sCO<sub>2</sub>-Flex Project

<https://www.sco2-flex.eu/>

sCO<sub>2</sub>- Flex aims at developing and validating the scalable/modular design of a 25MW<sub>e</sub> Brayton cycle using supercritical CO<sub>2</sub>, able to increase the operational flexibility and the efficiency of existing and future coal/lignite power plants

Bringing the sCO<sub>2</sub> cycle to TRL6

- global cycle assessment at simulation level
- boiler, heat exchangers and turbomachinery tested at relevant environment

Paving the way

- to future demonstration projects (from 2020)
- to commercialization of the technology (from 2025).

THE SCO<sub>2</sub>-FLEX PROJECT HAS RECEIVED FUNDING FROM THE EUROPEAN UNION'S HORIZON 2020 RESEARCH AND INNOVATION PROGRAMME UNDER GRANT AGREEMENT N° 764690

# The H2020 sCO<sub>2</sub>-Flex Project – Consortium

1. **EFD:** Project Coordinator
2. **Zabala:** Dissemination & communication
3. **BHGE:** Turbine/compressor design & testing
4. **UJV REZ:** Pulverized coal boiler development

## 10. POLIMI:

- Optimization of system design at nominal point
- Definition of optimal part-load operation strategy
- Evaluation of system dynamic
- **Cycle applications to other energy fields (CSP)**

Evaluate the off-design performance of  $s\text{CO}_2$  cycles for CSP application considering:

- **Part Load Operation**
  - Relevant for the future energy scenarios with high VRE contribution
- **Variable Ambient Temperature Operation**
  - Relevant for  $s\text{CO}_2$  cycles using ambient air as heat sink

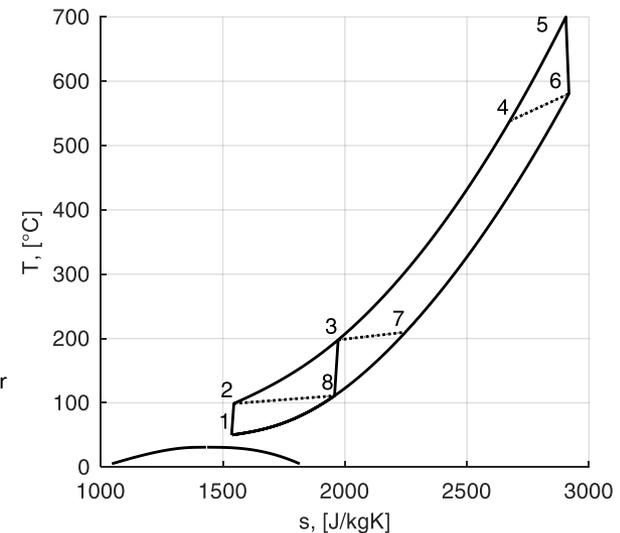

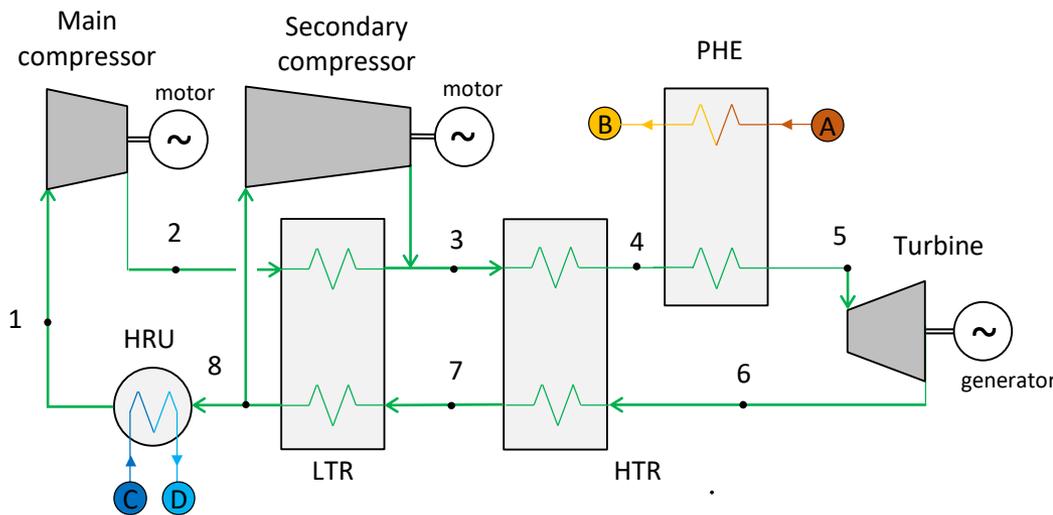

Obtain guidelines for turbomachinery design considering the system off-design operation

# Cycle Design – Assumptions

A  $s\text{CO}_2$  recompression cycle was selected as power conversion cycle

→ good compromise between performance and simplicity (1 Compr, 1 Turb).

Sodium at  $715^\circ\text{C}$  was considered as Heat Transfer Fluid providing heat to the cycle

## Main Cycle Assumptions

Parameter	Value	Parameter	Value
Cycle net electric power $W_{net}$ , $\text{MW}_{el}$	50	HTR/LTR pinch point $\Delta T_{HTR}/\Delta T_{LTR}$ , $^\circ\text{C}$	12
Maximum cycle temperature $T_5$ , $^\circ\text{C}$	700	HRU $\text{CO}_2$ pressure drop $(\Delta p/p_{in})_{HRU}$	0.5%
Maximum cycle pressure $p_2$ , bar	250	HTR/LTR hot side pressure drop $(\Delta p/p_{in})_{Hot,Rec}$	0.5%
Minimum cycle temperature $T_1$ , $^\circ\text{C}$	50	PHE $\text{CO}_2$ pressure drop $\Delta p_{PHE}$ , bar	2.5
Turbine isentropic efficiency, $\eta_{turb}$	93%	HRU electric consumption $\xi$ , $\text{MW}_{el}/\text{MW}_{th}$	0.0085
Main/secondary compressor efficiency, $\eta_{comp}$	89%	Design ambient temperature $T_{amb}$ , $^\circ\text{C}$	40

# Cycle Design – Thermodynamic Results

- A numerical code that solves mass and energy balances has been developed in MATLAB + Refprop
- Optimization variables:  $p_{\min}$  and  $p_{\max}$
- Objective function:  $\eta_{\text{cycle}}$

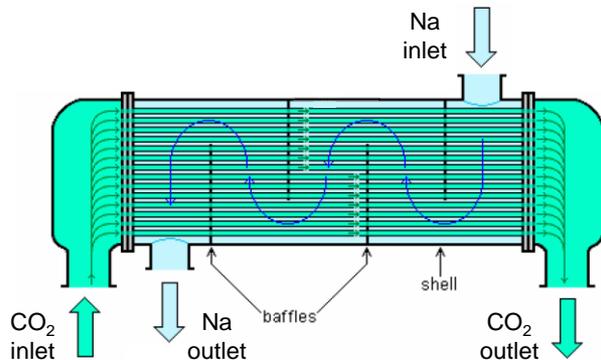

Main Cycle Design Results			
CO <sub>2</sub> mass flow at turbine inlet, kg/s	531.9	Main compressor electric power, MW <sub>el</sub>	12.1
CO <sub>2</sub> mass flow at HRU, kg/s	375.1	Secondary compressor electric power, MW <sub>el</sub>	10.2
Minimum cycle pressure $p_1$ , bar	<b>104.1</b>	Heat rejection auxiliaries consumption, MW <sub>el</sub>	0.47
HTR cold side $(\Delta p/p_{\text{in}})_{\text{Cold,HTR}}$	0.08%	Heat recuperated in the HTR $\dot{Q}_{\text{HTR}}$ , MW <sub>th</sub>	232.7
LTR cold side $(\Delta p/p_{\text{in}})_{\text{Cold,LTR}}$	0.04%	Heat recuperated in the LTR $\dot{Q}_{\text{LTR}}$ , MW <sub>th</sub>	66.7
Net heat input $\dot{Q}_{\text{in,cycle}}$ , MW <sub>th</sub>	108.7	Heat rejected to environment $\dot{Q}_{\text{HRU}}$ , MW <sub>th</sub>	54.8
Turbine electric power, MW <sub>el</sub>	72.8	Net Cycle efficiency	<b>46 %</b>

# Heat Exchangers Design – Assumptions

## Primary Heat Exchanger

- Shell and tube heat exchanger
- Seban-Shimazaki correlation for  $h_{Na}$
- Gnielinski correlation for  $h_{CO_2}$
- Material: INCONEL 617
- $CO_2$  pressure drop: 2.5 bar

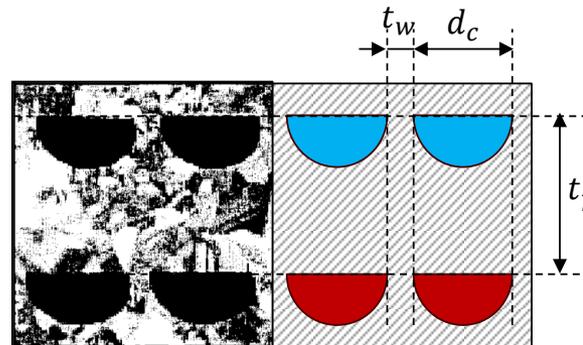

Parameter	Value
Tubes $d_{int}$ , mm	16
Tube pitch, $t_p$	$1.25d_{ext}$
Na max velocity $v_{Na}$ , m/s	0.25

## Recuperators

- Printed circuit heat exchanger
- Model based on Dostal PhD thesis
- Gnielinski correlation for  $h_{int}$
- Material: INCOLOY 800
- $CO_2$  pressure drop: 0.5%

Parameter	Value
Plate thickness $t_p$ , mm	1.5
Channel diameter $d_c$ , mm	2
Channel spacing $t_w$ , mm	0.4

## Heat Rejection Unit

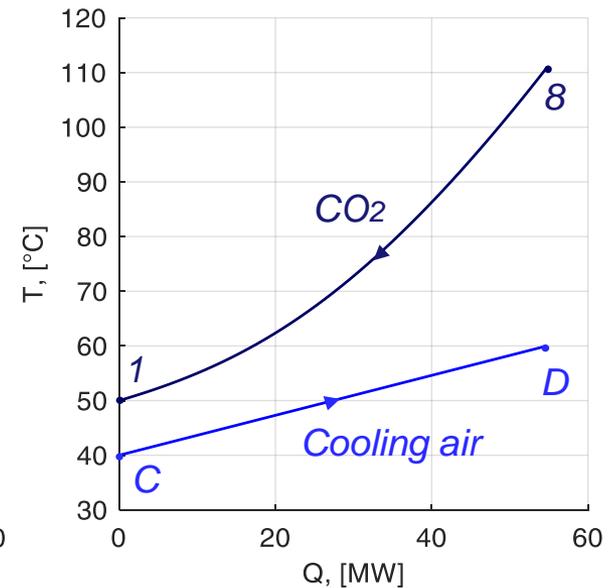

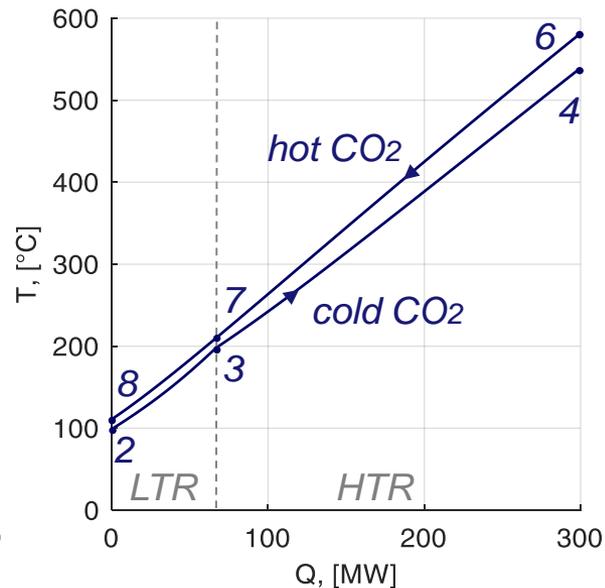

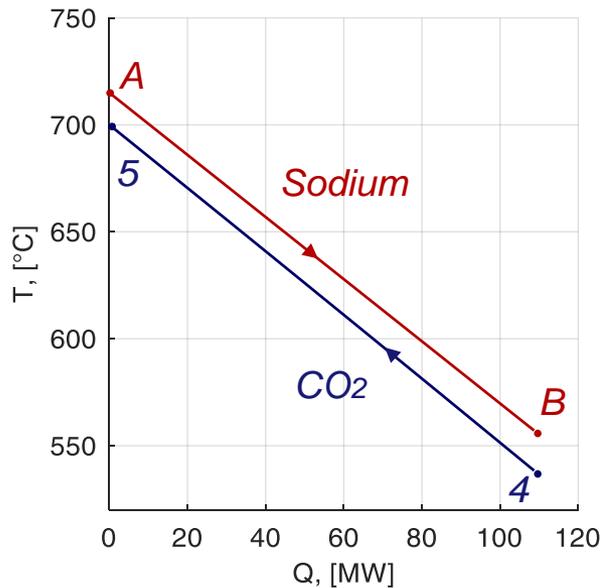

- Dry cooler tuned on manufacturer data
- Modified Gnielinski correlation for  $h_{int}$
- Material: copper + aluminum
- Fans with variable speed EM
- $CO_2$  pressure drop: 0.5%

Parameter	Value
$\Delta T_{air}$ , °C	16
Tube $d_{int}$ , mm	7.5
Fin thickness, mm	0.12
Fin spacing, mm	2.1
Fin height, mm	9.1

# Heat Exchangers Design – Results

Parameter	HRU	LTR	HTR	PHE
Heat duty, MW	54.8	66.7	232.7	108.7
Hot side h.t.c., W/m <sup>2</sup> K	3821.9	2163.3	1637.4	14291.5
Cold side h.t.c., W/m <sup>2</sup> K	75.8	2143.7	1741.9	3392.5
<b>Global h.t.c., W/m<sup>2</sup>K</b>	<b>1079.2</b>	<b>1033.1</b>	<b>820.0</b>	<b>2078.8</b>
Internal surface, m <sup>2</sup>	2713.2	4666.5	9796.7	3160.1
HX metal mass, kg	21406.8	29261.1	61429.6	140873.0
<b>CO<sub>2</sub> inventory, kg</b>	<b>2353.2</b>	<b>390.6</b>	<b>427.6</b>	<b>5400.1</b>

HX sizing results (heat transfer areas) are used as input for the off-design study

# Off-design Simulation: Methodology and Assumptions

- A MATLAB + Refprop code to simulate off-design operation of the selected sCO<sub>2</sub> cycle has been developed
- The codes requires as input:
  - Sodium mass flow rate
  - Sodium temperature
  - Ambient conditions
  - Components' constrains ( $A_{HX}, \dots$ ) from the design simulation
  - Information about the selected control strategy
- The code solves a system of non-linear equations and obtains off-design thermodynamic operating points and performances

# Off-design Simulation: Methodology and Assumptions

The following hypotheses/constraints have been also assumed:

- $\Delta p$  and h.t.c. varied according to exponential laws for all HXs:

$$\Delta p = \Delta p_{design} \left( \frac{\rho_{design}}{\rho} \right) \left( \frac{\dot{m}}{\dot{m}_{design}} \right)^2 \quad h_X = h_{X,design} \left( \frac{\dot{m}_X}{\dot{m}_{X,design}} \right)^\alpha$$

- HRU fan consumption computed through exponential correlation:

$$\dot{W}_{HRU,aux} = \dot{W}_{HRU,aux,design} \left( \frac{\dot{m}_{air}}{\dot{m}_{air,design}} \right)^{2.78}$$

- Isothermal mixing at the HTR inlet
- Turbine in choked flow conditions and sliding pressure (no VIGV) and with constant  $T_{in,turb}$ :

$$\frac{\dot{m}_{in,turb}}{p_{in,turb}} = const$$

- **Constant turbomachinery efficiency at part-load**
- **No specific constraints for the compressors:** the obtained operating points in off-design are meant to provide useful preliminary design criteria

# Part Load Analysis – Control Strategy of Closed Gas Cycles

## Closed Ideal gas cycle control

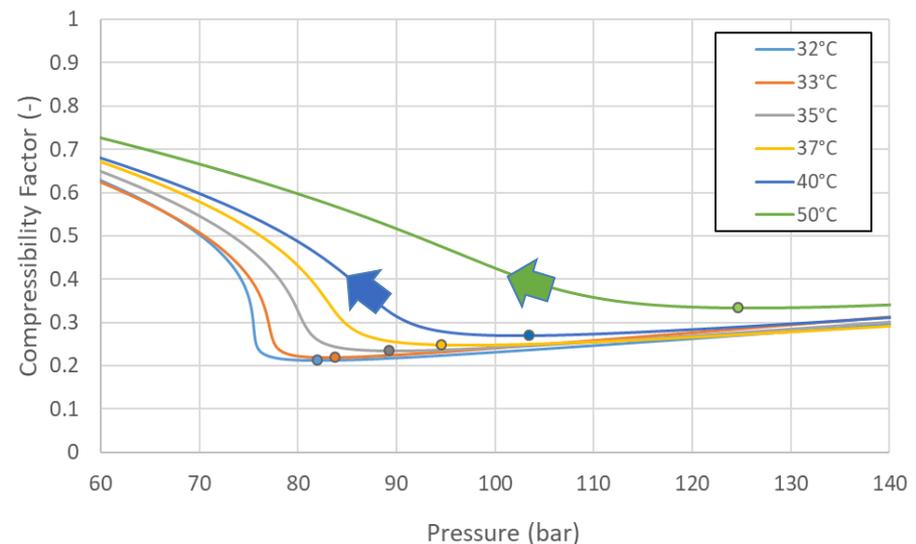

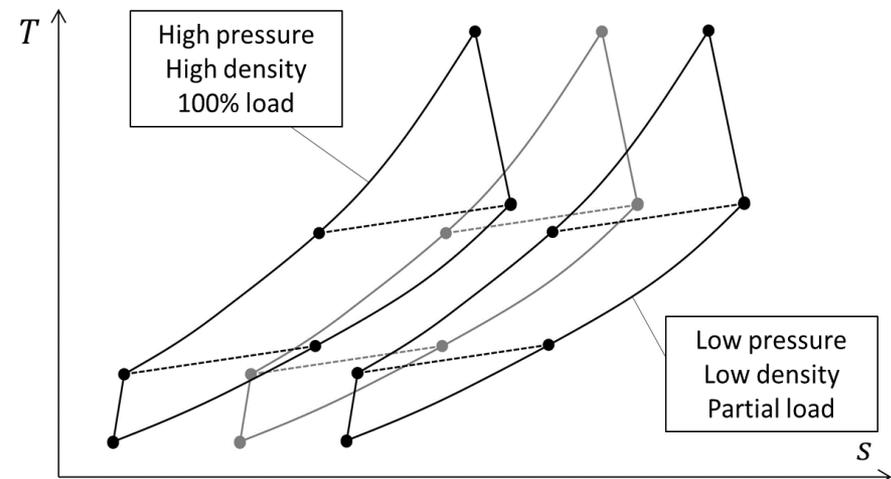

It can be obtained by cycle depressurization removing a fraction of the working fluid mass with constant compression ratio ( $\beta$ ) and thus with constant efficiency.

$$P = \dot{m}(w_t - w_c); \quad \eta = 1 - \beta^{-\theta}$$

## sCO<sub>2</sub> cycles control

Equal reduction of maximum and minimum cycle pressure (constant  $\beta$ ) may not be convenient for sCO<sub>2</sub> cycles due to the compressor proximity to critical point.

A reduction of the minimum pressure may imply strong increase of the compressor work and thus  $\eta \downarrow$

# Part Load Analysis – Operating Strategies

As the Sodium mass flow rate decreases the maximum cycle pressure decreases (sliding pressure). Three operating strategies have been investigated for the minimum cycle pressure:

- CASE 1: minimum cycle pressure kept equal to the design value
- CASE 2 : minimum cycle pressure optimized to obtain maximum cycle efficiency
- CASE 3: minimum cycle pressure varied in order to guarantee a constant  $\Delta T_{Na}$  across the PHX

Further assumption:

- No ambient temperature variation

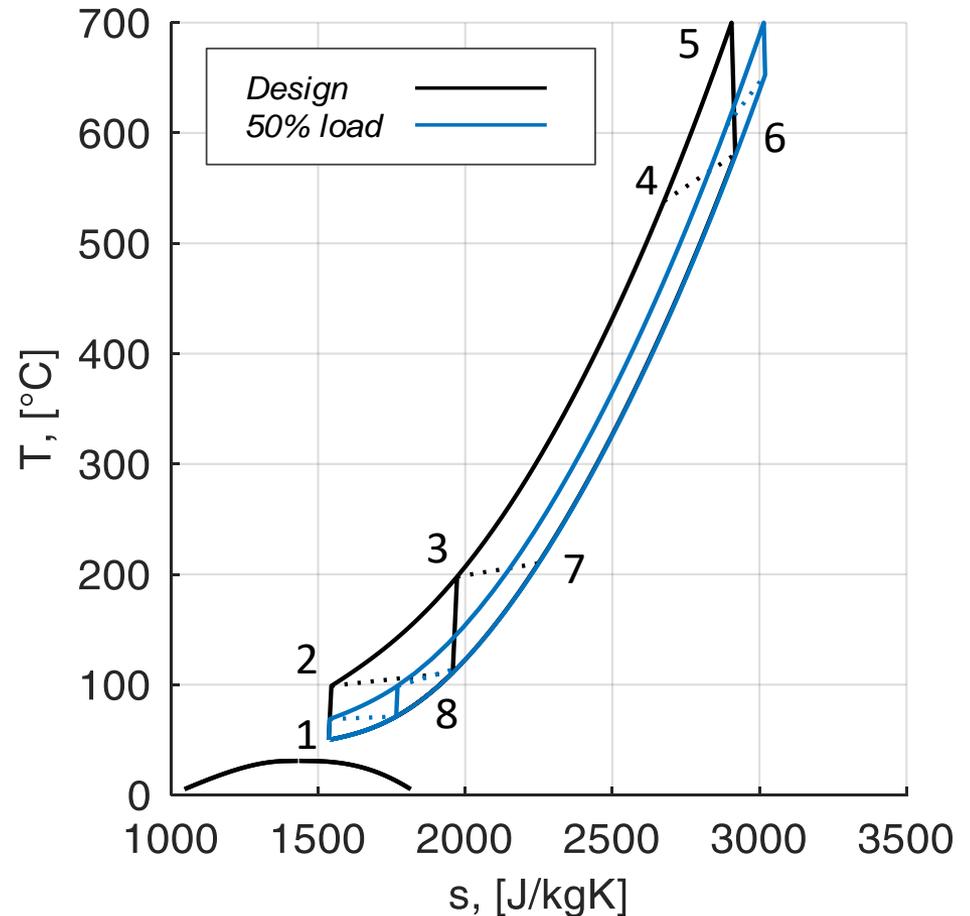

# CASE 1: $p_{\min}$ equal to the design value

When the HTF mass flow rate is reduced:

Maximum cycle pressure is reduced leading to higher temperature at PHE (point 4) but also lower temperature at HTR bypass inlet (point 3)

Cycle pressure ratio reduces with penalizing effects on cycle efficiency

Heat exchangers show higher effectiveness because of the lower duty and temperature differences reduce with positive effects on cycle performance

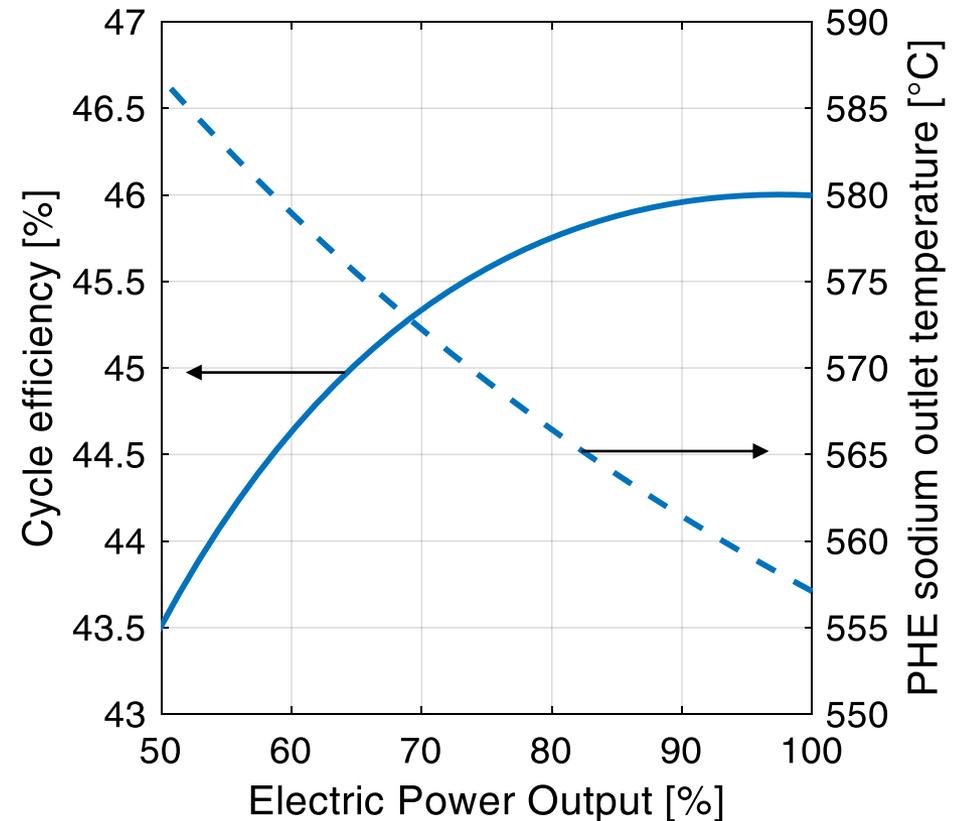

# CASE 1: $p_{\min}$ equal to the design value

When the HTF mass flow rate is reduced:

Maximum cycle pressure is reduced leading to higher temperature at PHE (point 4) but also lower temperature at HTR bypass inlet (point 3)

Cycle pressure ratio reduces with penalizing effects on cycle efficiency

Heat exchangers show higher effectiveness because of the lower duty and temperature differences reduce with positive effects on cycle performance

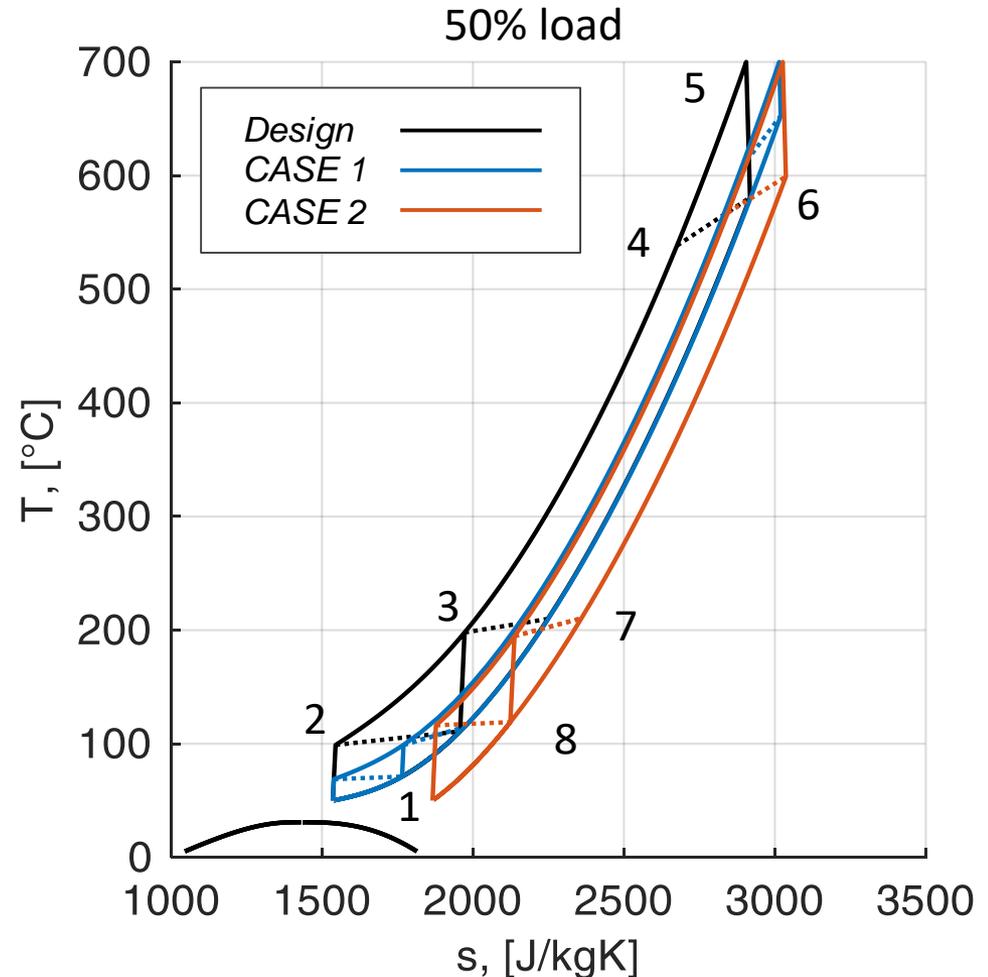

## CASE 2: optimized $p_{\min}$

CASE2 is obtained by optimizing for each part-load the cycle minimum pressure to obtain the maximum cycle efficiency.

When the HTF flow rate is reduced:

A reduction of the cycle minimum pressure limits the penalization related to the cycle compression ratio reduction

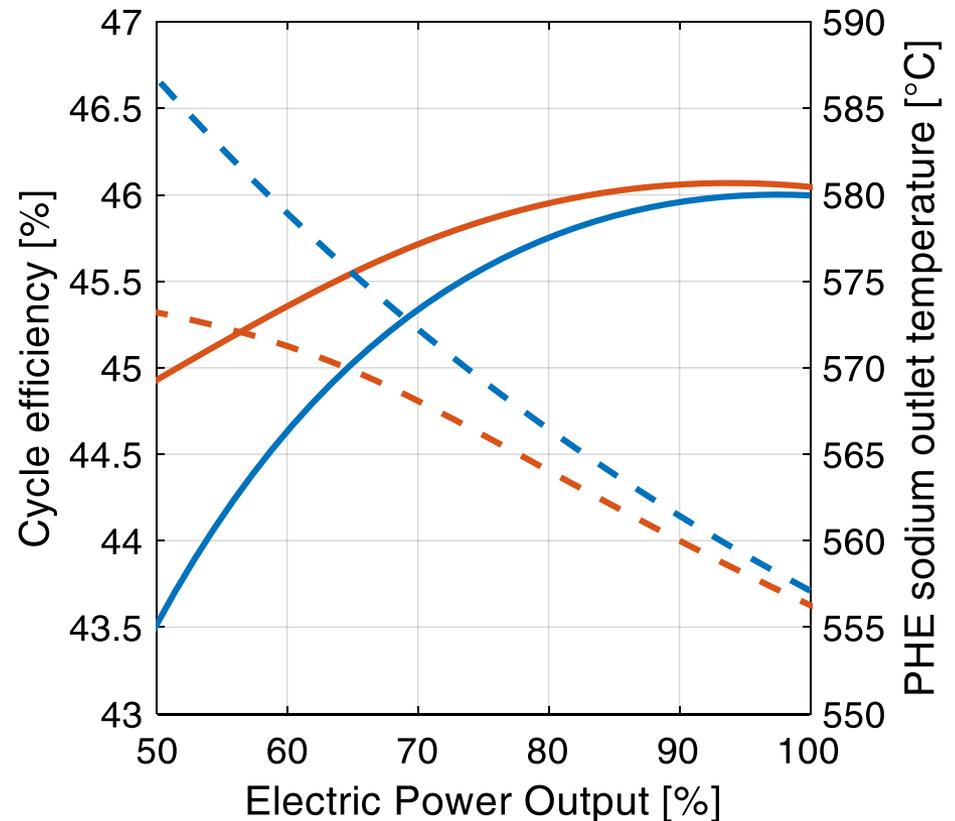

## CASE 2: optimized $p_{\min}$

CASE2 is obtained by optimizing for each part-load the cycle minimum pressure to obtain the maximum cycle efficiency.

When the HTF flow rate is reduced:

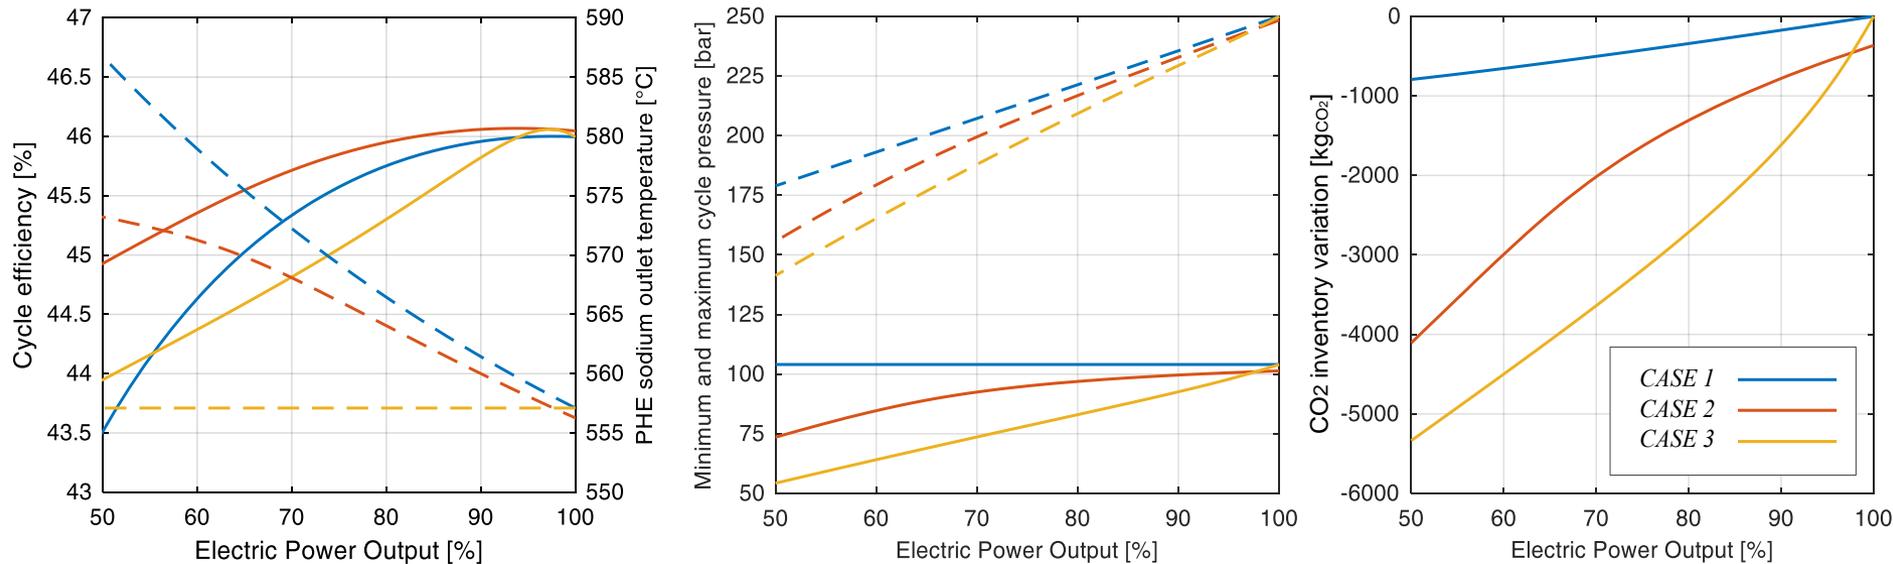

A reduction of the cycle minimum pressure limits the penalization related to the cycle compression ratio reduction

The cycle efficiency at 50% load can be increased by 1.5 percent point with respect to CASE 1

## CASE 3: $\Delta T_{Na} = \text{const}$

The minimum cycle pressure is obtained through a sensitivity analysis in order to keep a constant HTF temperature variation across the PHX.

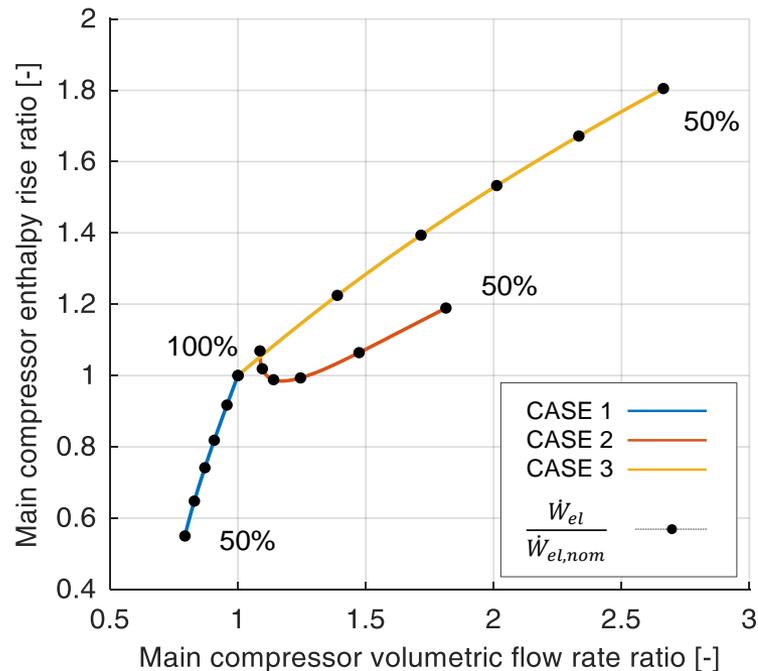

CASE 3 performs poorly as keeping  $\Delta T_{Na} = \text{const}$  requires a continuous reduction of the minimum cycle pressure immediately shifting the compressor inlet away from the critical point.

All CASEs require a tank to store the excess CO<sub>2</sub> extracted from the cycle. CASE 3 implies also the maximum CO<sub>2</sub> inventory variation.

# Part Load Analysis – Considerations on Compressors Design

The main compressor operating points for CASE1-3 reported in a dimensionless  $\Delta h - \dot{V}$  diagram show strongly different trends.

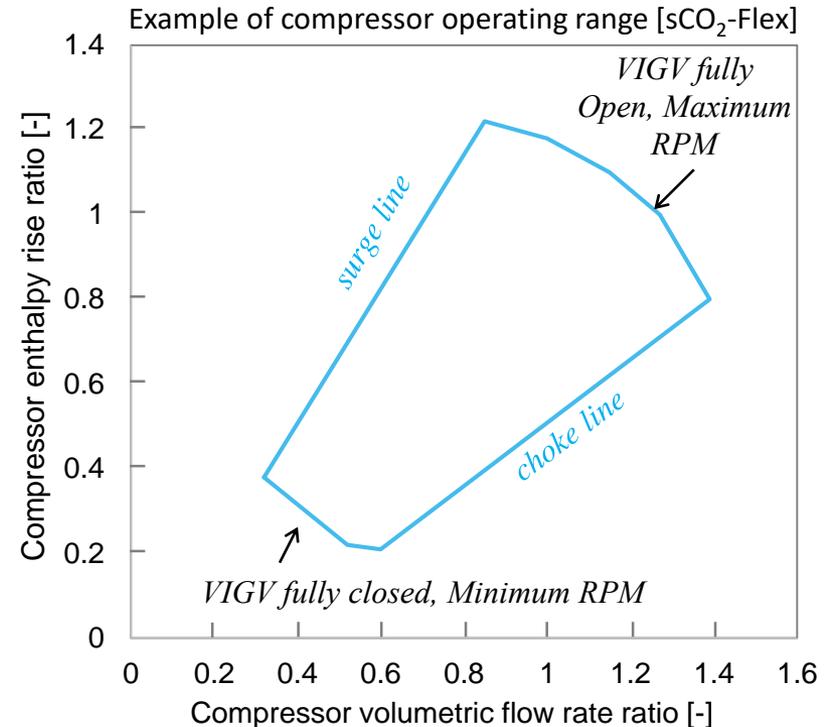

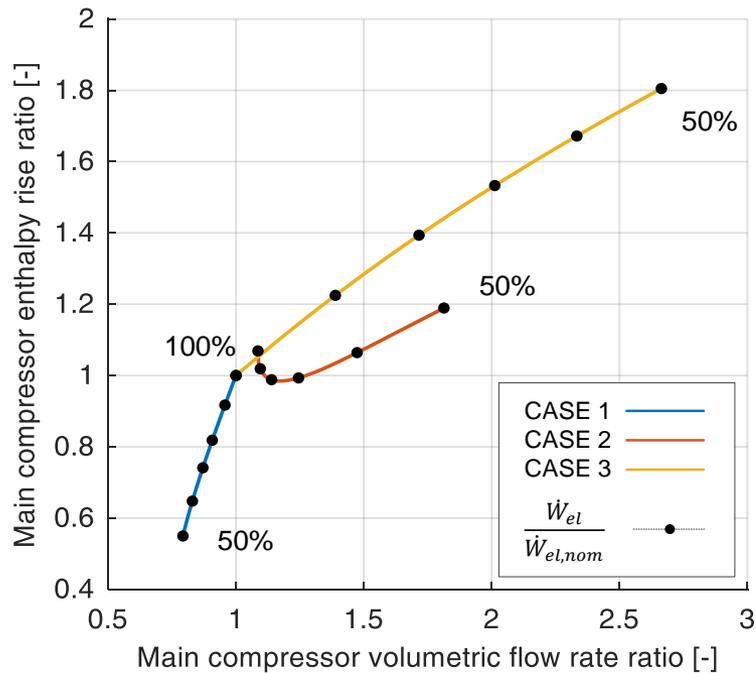

In CASE 1 both  $\dot{V}$  and  $\Delta h$  reduce with the load (HTF mass flow rate):

- cycle  $\beta \downarrow \rightarrow \Delta h \downarrow$
- $\rho_1(T, P) = const \rightarrow \dot{V}_1 = \frac{\dot{m}_{CO_2}}{\rho_1} \downarrow$

In CASE 2-3 the compressor inlet shifts away from the critical point thus both  $\dot{V}$  and  $\Delta h$  increase

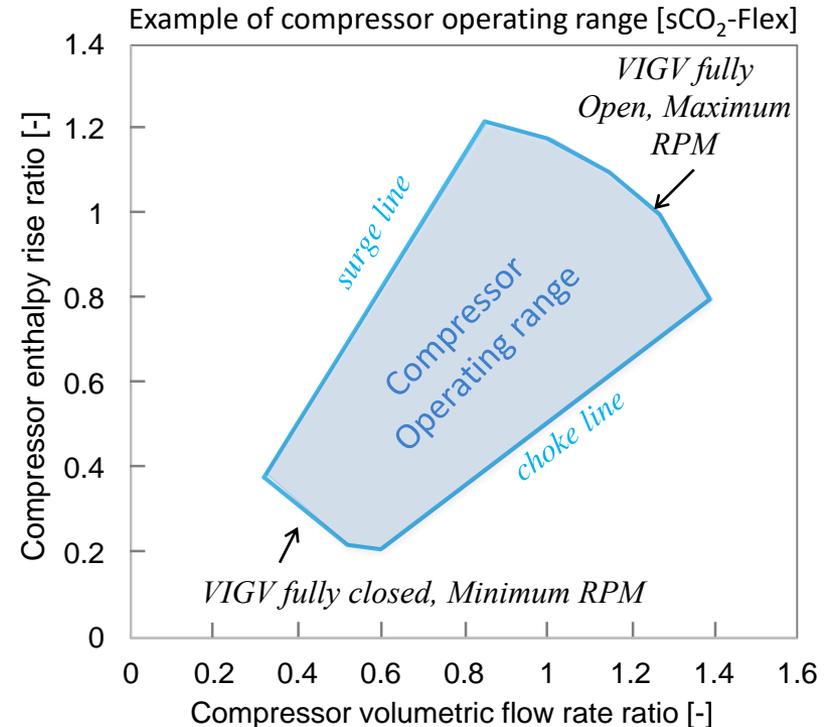

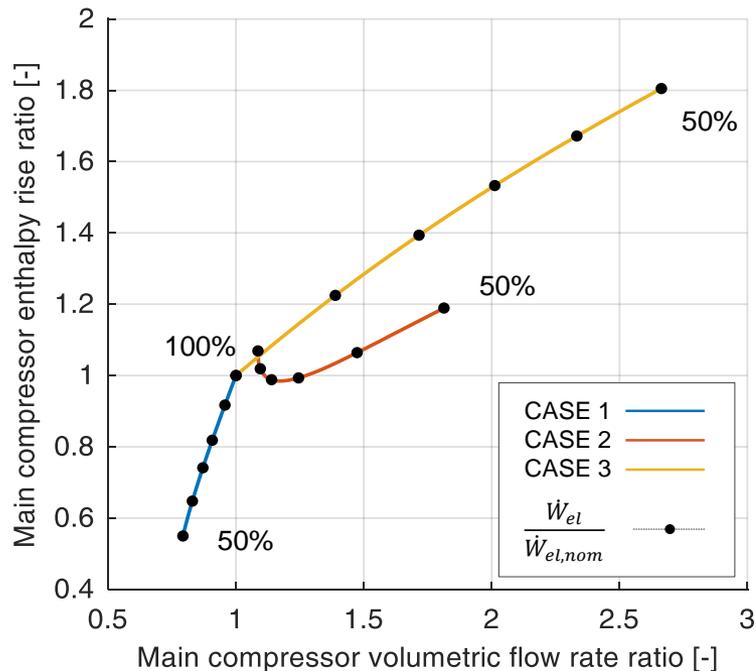

# Part Load Analysis – Considerations on Compressors Design

The main compressor operating points for CASE1-3 reported in a dimensionless  $\Delta h - \dot{V}$  diagram show strongly different trends.

# Part Load Analysis – Considerations on Compressors Design

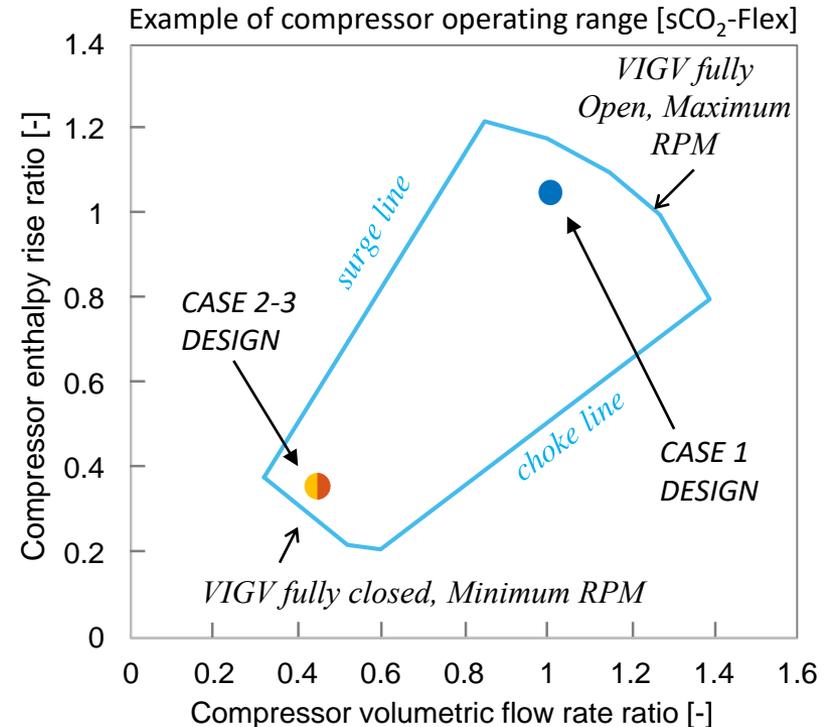

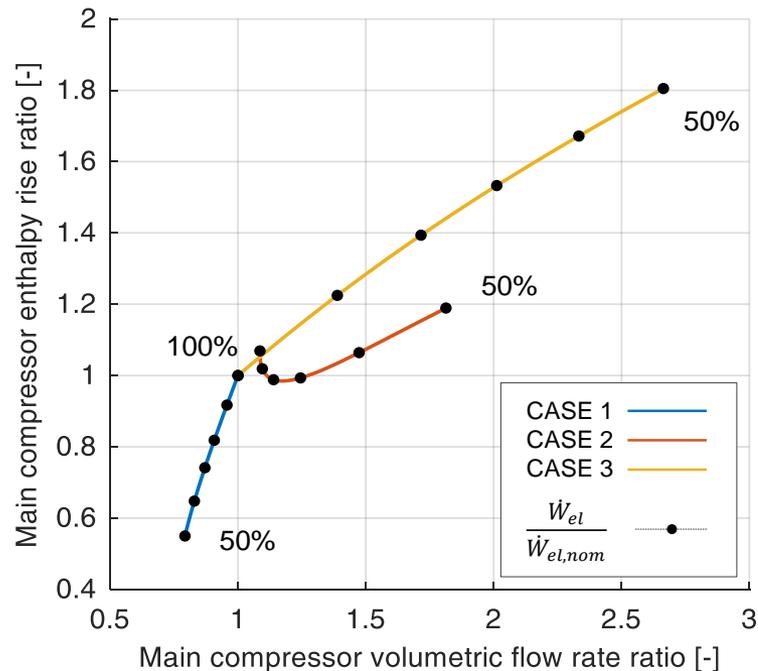

The main compressor operating points for CASE1-3 reported in a dimensionless  $\Delta h - \dot{V}$  diagram show strongly different trends.

- The operating point of the compressor can be varied acting on VIGV and on RPM.

# Part Load Analysis – Considerations on Compressors Design

The main compressor operating points for CASE1-3 reported in a dimensionless  $\Delta h - \dot{V}$  diagram show strongly different trends.

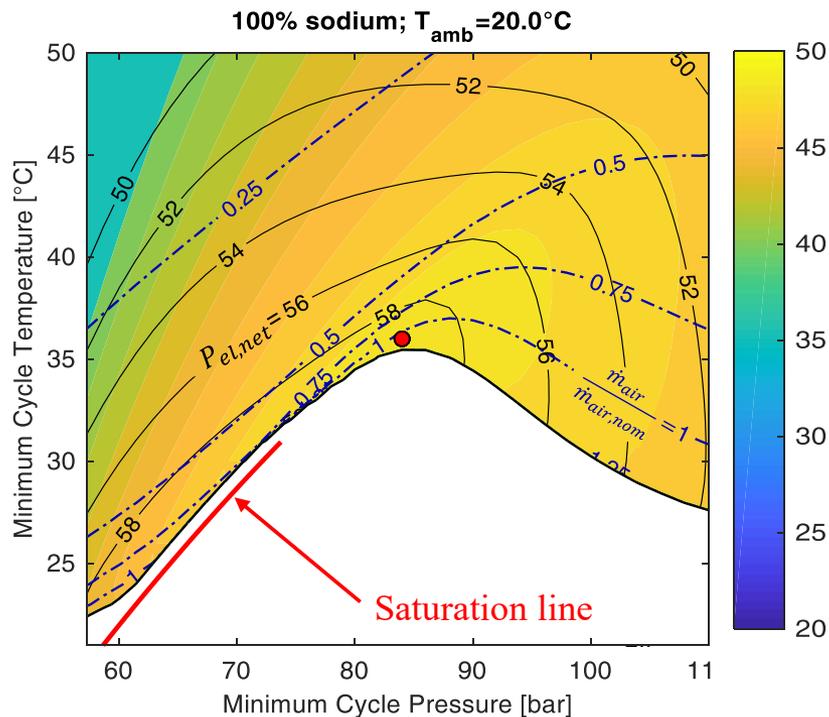

- The operating point of the compressor can be varied acting on VIGV and on RPM
- CASE1-3 design point needs to be significantly different.
- Further degrees of freedom may be obtained using 2 series/parallel compressors or acting on the split ratio between primary and secondary compressor.

# Variable Ambient Temperature Analysis

For a given ambient temperature minimum cycle T and P have been parametrically investigated to find the best operating point (maximum efficiency).

The selected T and p can be obtained by varying **HRU fan speed** and **fluid inventory**.

Design:  $\left\{ \begin{array}{l} T_{amb} = 40^\circ\text{C} \\ T_1 = \text{CIT} = 50^\circ\text{C} \\ P_1 = 104.1 \end{array} \right.$

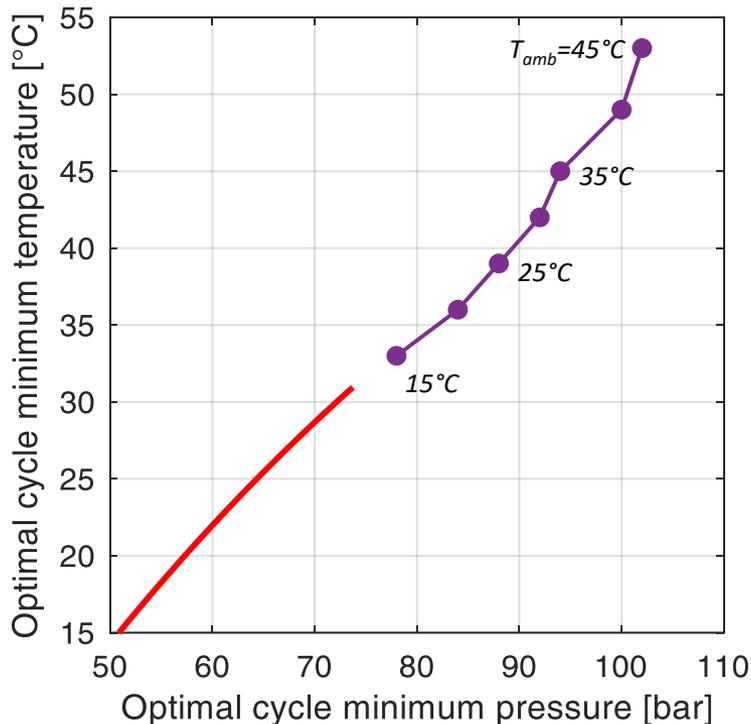

With lower ambient temperature it is preferred to keep the HRU fan speed at maximum reducing the compression work (CIT  $\downarrow$ ).

As  $T_{amb}$  reduces the best operation moves towards the critical point minimizing the compression work.

# Variable Ambient Temperature Analysis

For a given ambient temperature minimum cycle T and P have been parametrically investigated to find the best operating point (maximum efficiency).

The selected T and p can be obtained by varying **HRU fan speed** and **fluid inventory**.

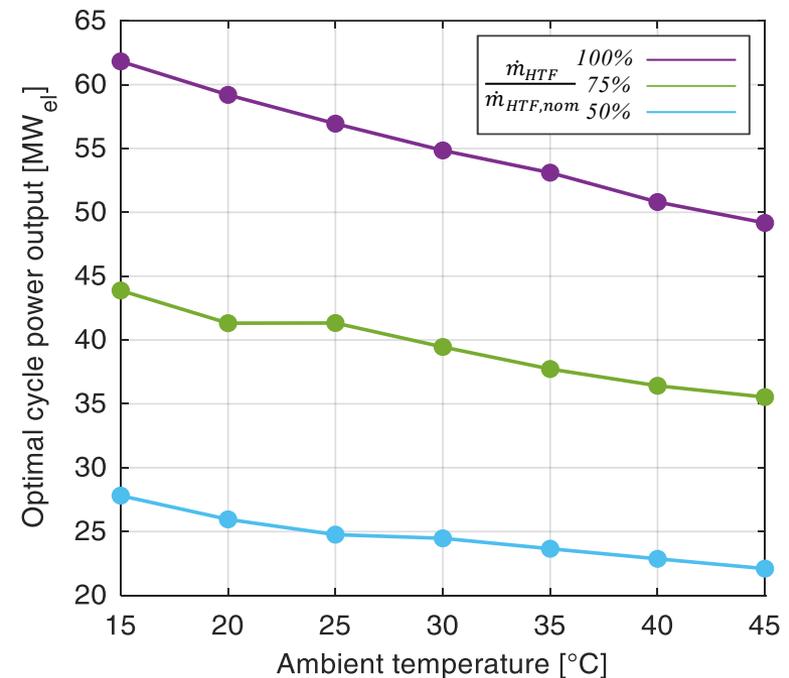

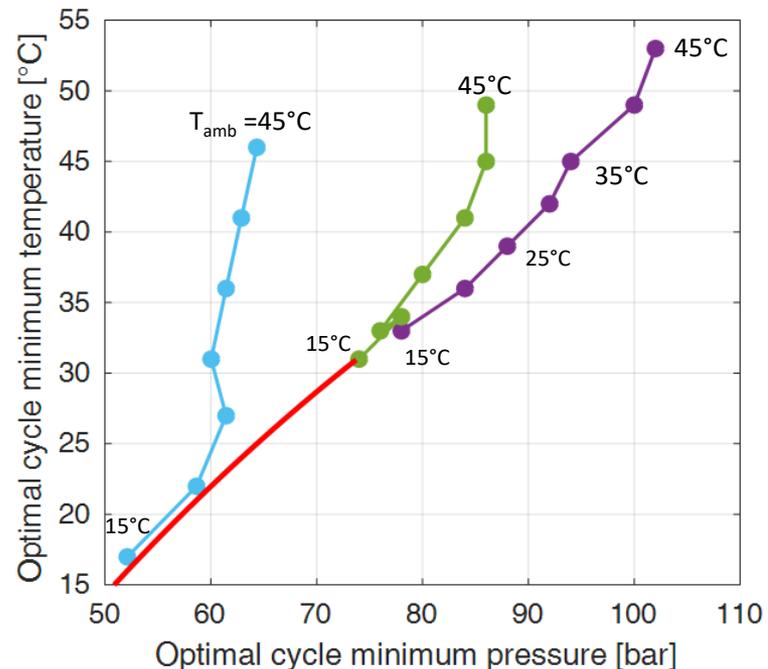

$$\text{Design: } \begin{cases} T_{amb} = 40^{\circ}\text{C} \\ T_1 = \text{CIT} = 50^{\circ}\text{C} \\ P_1 = 104.1 \end{cases}$$

With lower ambient temperature it is preferred to keep the HRU fan speed at maximum reducing the compression work (CIT ↓).

As  $T_{amb}$  reduces the best operation moves towards the critical point minimizing the compression work.

# Variable Ambient Temperature AND Part Load Analysis

- The combined effect of **variable ambient temperature** and **variable sodium mass flow rate** was finally investigated.
- At 50% load a stronger CIT reduction is obtained, but no condensation occurs.
- The best operating point is thus obtained for **every ambient temperature** and **every load**.

# Conclusions

- Part load analysis of sCO<sub>2</sub> power plants is a topic poorly investigated in literature and guidance and/or best strategies are still missing
- A tool for the evaluation of the off-design performance of sCO<sub>2</sub> cycles has been developed
- The minimum cycle pressure optimization allows to increase the plant efficiency at part-load, with a stronger inventory variation (larger sCO<sub>2</sub> storage)
- The design of the main compressor should allow an increase of  $\Delta h$  and  $\dot{V}$  at part-load operation
- The design of the Heat Rejection Unit should consider the variation of the ambient temperature for the selected site

- Implementation of performance maps for turbomachinery in order to account for components efficiency variation
- Introduction of other possible control options such as anti-surge valves, split ratio variation in off-design operation, reduction of the maximum cycle temperature
- Evaluate yearly performance of CSP plants using sCO<sub>2</sub> cycle maximizing the energy output or the system economic performances
- Evaluate the best HRU and compressor design to maximize the yearly energy output

**Thanks for your attention!**
